Nutritious milk from moms to babies

In a recent study, it was found that breast milk contains a special kind of protein that is beneficial to the digestive system of babies. When this protein is introduced to the babies, it helps to improve their immune system and overall health.

The study was conducted on a group of babies aged 6 months and older. The babies were divided into two groups: one group was fed breast milk, while the other group was fed formula milk. The results showed that babies fed breast milk had a lower incidence of infections and a faster recovery from illnesses compared to those fed formula milk.

Experts believe that this protein in breast milk plays a crucial role in the development of a baby's immune system. It is important for parents to ensure that their babies are fed breast milk as much as possible, especially during their first year of life.
